## UNIVERSITY OF OSLO DEPARTMENT OF ECONOMICS

Postponed exam: ECON4310 - Macroeconomic Theory
Date of exam: Tuesday, January 9, 2018
Time for exam: 09:00 a.m. - 12:00 noon
The problem set covers 11 pages (incl. cover sheet)
Resources allowed:

- No written or printed resources - or calculator - is allowed (except if you have been granted use of a dictionary from the Faculty of Social Sciences)

The grades given: A-F, with A as the best and E as the weakest passing grade. F is fail.

## Final Exam (retake) ECON 4310, Fall 2017

1. Do not write with pencil, please use a ball-pen instead.
2. Please answer in English. Solutions without traceable outlines, as well as those with unreadable outlines do not earn points.
3. Please start a new page for every short question and for every subquestion of the long questions.

## Good Luck!

|  | Points | Max |
| :--- | :--- | :---: |
| Exercise A |  | 40 |
| Exercise B |  | 60 |
| Exercise C |  | 60 |
| $\Sigma$ |  | 160 |

Grade:

## Exercise A: <br> Short Questions (40 Points)

Answer each of the following short questions on a seperate answer sheet by stating as a first answer True/False and then give a short but instructive explanation. You can write, calculate, or draw to explain your answer. You only get points if you have stated the correct True/False and provided a correct explanation to the question. We will not assign negative points for incorrect answers.

## Exercise A.1: (10 Points) The Optimal Capital Stock

Because more capital allows more output to be produced, it is always better for a country to have more capital stock. True or false?

Your Answer:
True: $\square$
False:

## Don't forget the explanation!

## Exercise A.2: (10 Points) Savings and Economic Growth

An economy that increases its saving rate will experience faster growth. True or false?

Your Answer:
True: $\square \quad$ False:
Don't forget the explanation!

## Exercise A.3: (10 Points) Finite horizon model of intertemporal consumption

Consider the optimal intertemporal consumption choice of a household in discrete and finite time $t=0,1, \ldots, T<\infty$. The optimal behavior is characterized by the consumption Euler equation

$$
\frac{c_{t+1}}{c_{t}}=[\beta(1+r)]^{1 / \theta}, \forall t \leq T,
$$

and the private bugdet constraint

$$
a_{t+1}+c_{t}=(1+r) a_{t}+w, \forall t \leq T,
$$

taking as given initial and terminal conditions

$$
\begin{aligned}
a_{0} & =0 \\
a_{T+1} & =0,
\end{aligned}
$$

where $a_{t}$ denotes asset holdings, $r$ is the exogenous interest rate, $w$ is the constant and exogenously given wage income, $c_{t}$ the individual consumption of the household, $\beta \in(0,1)$ is the subjective discount factor, and $1 / \theta$ the intertemporal elasticity of substitution.

Suppose that $\beta(1+r)=0.98$ and $\theta=1$. Then this household will first accumulate strictly positive assets for a while and then run down assets over the life-cycle. True or false?

## Your Answer:

True: $\square$
False:

## Don't forget the explanation!

## Exercise A.4: (10 Points) Capital and skilled labor complementarity in Solow model

Consider the following version of the Solow model with two types of workers, skilled workers and unskilled workers. The number of workers are given by $S$ and $U$, respectively. There are no population growth or technology growth. The production function is specified in (2), and the economy is described by the following equations

$$
\begin{align*}
K_{t+1} & =s Y_{t}+(1-\delta) K_{t}  \tag{1}\\
Y_{t} & =\left(\phi_{1}\left[\phi_{2} K_{t}^{\frac{\rho-1}{\rho}}+\left(1-\phi_{2}\right) S^{\frac{\rho-1}{\rho}}\right]^{\frac{\rho}{\rho-1} \frac{\sigma-1}{\sigma}}+\left(1-\phi_{1}\right) U^{\frac{\sigma-1}{\sigma}}\right)^{\frac{\sigma}{\sigma-1}}, \tag{2}
\end{align*}
$$

where $0<\delta<1$ is the depreciation rate of physical capital, and the saving rate $s$ is constant. $\phi_{1}, \phi_{2} \rho, \sigma$ are also constant parameters. Denote the share of skilled workers as $\theta \equiv \frac{S}{L}=\frac{S}{S+U}$.

The steady-state level of the capital stock per capita, $k_{t} \equiv K_{t} / L$, is described by

$$
\delta k^{\star}=s\left(\phi_{1}\left[\phi_{2}\left(k^{\star}\right)^{\frac{\rho-1}{\rho}}+\left(1-\phi_{2}\right) \theta^{\frac{\rho-1}{\rho}}\right]^{\frac{\rho}{\rho-1} \frac{\sigma-1}{\sigma}}+\left(1-\phi_{1}\right)(1-\theta)^{\frac{\sigma-1}{\sigma}}\right)^{\frac{\sigma}{\sigma-1}} .
$$

True or false?

Your Answer:
True:
False:
Don't forget the explanation!

## Exercise B: <br> Long Question (60 Points)

## Temporary fiscal shocks in the Ramsey model

Consider a discrete-time version of Ramsey's growth model. The economy is closed and we consider a representative agent with the following preferences over consumption

$$
\begin{equation*}
U=\sum_{t=0}^{\infty} \beta^{t} u\left(c_{t}\right), \tag{3}
\end{equation*}
$$

where $c_{t}$ denotes period $t$ consumption and $\beta \in(0,1)$ is the subjective discount factor. The momentary utility function is of the form

$$
u\left(c_{t}\right)=\frac{c_{t}^{1-\theta}-1}{1-\theta}
$$

with $\theta>1$. Every period the agent earns a wage $w_{t}$ (the labor supply is exogenously set to 1 unit), an interest $r_{t} a_{t}$ from her assets holdings and she is subject to the lump-sum tax $\tau_{t}$. In equilibrium, the agent will choose the sequence consumption and asset holdings $\left\{c_{t}, a_{t+1}\right\}_{t=0}^{\infty}$ to maximize $U$ subject to the period-by-period budget constraint

$$
\begin{equation*}
c_{t}+a_{t+1}=w_{t}+\left(1+r_{t}\right) a_{t}-\tau_{t} \tag{4}
\end{equation*}
$$

for a given $a_{0}$. The agent is atomic and her decisions do not influence aggregate variables, thus she takes the sequence of taxes, wage rates and interest rates as given.

## Firms:

The firm is atomic and acts as a price-taking profit maximizer. Capital can be rented at the rental rate $R_{t}=r_{t}+\delta$ (note that the depreciation rate $\delta$ is the difference between the rental rate and the interest rate) while labor costs $w_{t}$.

The representative firm demands physical capital $k_{t}$ and labor $n_{t}$ to produce output $y_{t}$ with the Cobb-Douglas technology

$$
\begin{equation*}
y_{t}=k_{t}^{\alpha} n_{t}^{1-\alpha} . \tag{5}
\end{equation*}
$$

## Governments:

The government can raise lump-sum taxes $\tau_{t}$ and rolls over debt in the form of oneperiod bonds, $D_{t+1}$, to finance government expenditure, $G_{t}$. As it pays an interest rate $r_{t}$ on the outstanding debt, $D_{t}$, the government faces a period-by-period budget constraint

$$
\begin{equation*}
G_{t}=\tau_{t}+D_{t+1}-\left(1+r_{t}\right) D_{t} \tag{6}
\end{equation*}
$$

Moreover, assume that the time path of government debt is such that it is growing at a lower rate than the interest rate

$$
\lim _{T \rightarrow \infty} \frac{D_{T+1}}{\prod_{s=0}^{T}\left(1+r_{s}\right)}=0
$$

In other words, it is not feasible for the government to finance the outstanding debt (plus interest payments) by issuing ever more debt as time goes by.
(a) (15 Points) Formulate the Lagrangian of the agent's decision problem (it is common to use $\lambda_{t}$ as the Lagrange multiplier on the period $t$ budget constraint).
Derive the first-order conditions for the optimal choice of $c_{t}$ and $a_{t+1}$.
(b) (5 Points) Derive the Consumption Euler Equation.
(c) (10 Points) Find the first-order conditions for the firm's optimization problem. Show that firms earn zero profits.
(d) (10 Points) Use the government's budget constraint in Equation (6) and substitute for $D_{t}$ iteratively $(t=1,2,3, \ldots)$ to derive the government's intertemporal budget constraint in net present value (NPV) terms

$$
\begin{equation*}
D_{0}=\sum_{t=0}^{\infty} \frac{\tau_{t}-G_{t}}{\prod_{s=0}^{t}\left(1+r_{s}\right)} \tag{7}
\end{equation*}
$$

Give an interpretation of Equation (7).
(Hint: you could start out with $D_{0}=\frac{1}{1+r_{0}}\left[\tau_{0}-G_{0}+D_{1}\right]$, and find a similar expression for $D_{1}$ and substitute it into the expression for $D_{0}$; do it iteratively.)

## Dynamics:

In this economy we know that the solution to the social planner's problem is equivalent to the competitive market equilibrium. According to the social planner's solution, the same consumption Euler equation and resource constraint (goods market clearing) along with the so-called transversality condition (which stands in for the no-Ponzi condition)

$$
\begin{aligned}
\frac{c_{t+1}}{c_{t}} & =\left[\beta\left(1+r_{t+1}\right)\right]^{1 / \theta}=\left[\beta\left(1+\alpha k_{t+1}^{\alpha-1}-\delta\right)\right]^{1 / \theta} \\
k_{t+1}-k_{t} & =k_{t}^{\alpha}-\delta k_{t}-c_{t}-G_{t} \\
\lim _{t \rightarrow \infty} \beta^{t} c_{t}^{-\theta} k_{t+1} & =0
\end{aligned}
$$

determine the optimal solution of the dynamic system. Let us assume that $G_{t}=G$, then we can define two correspondances. One which characterizes all possible combinations of $\left(c_{t}, k_{t}\right)$ when consumption is constant,

$$
\mathcal{C}_{1}(k) \equiv\left\{c \in[0, \infty): c_{t+1} / c_{t}=\left[\beta\left(1+\alpha k^{\alpha-1}-\delta\right)\right]^{1 / \theta}, c_{t+1}=c_{t}=c\right\}
$$

and one which captures all combinations if the physical capital stock is constant,

$$
\mathcal{C}_{2}(k) \equiv\left\{c \in[0, \infty): c=k_{t}^{a}-\left(k_{t+1}-(1-\delta) k_{t}\right)-G, k_{t+1}=k_{t}=k\right\}
$$

(e) (10 Points) Draw the two correspondances, $\mathcal{C}_{1}(k)$ and $\mathcal{C}_{2}(k)$, in a diagram with $k$ on the horizontal axis and $c$ on the vertical axis, the so called phase diagram.
(f) (10 Points) Now assume that the economy has run for a long time and is in its steady state with constant government expenditures, $G_{t}=G$, and tax policy, $\tau_{t}=$ $\tau$.
Consider an unexpected and temporary increase of $\Delta G$ in government expenditures from period $t_{0}$ until period $t_{1}$. Sketch the dynamics of consumption and physical capital back to the steady-state in the phase diagram.

## Exercise C: <br> Long Question (60 Points)

## Labor supply and Real business Cycle Model

Consider a real business cycle model with only technology shocks. The representative household is endowed with one unit of time each period and has expected lifetime utility of,

$$
\begin{equation*}
E_{0} \sum_{t=0}^{\infty} \beta^{t}\left[\ln \left(c_{t}\right)+\frac{\left(1-l_{t}\right)^{\theta}}{\theta}\right], \quad 1>\theta>0 \tag{8}
\end{equation*}
$$

where $c$ is per capita consumption and $l$ is the amount of time spent working. Assume $0<\theta<1$. Capital depreciates at rate $\delta$. Denote the real interest rate by $r_{t}$, and the wage rate by $w_{t}$. Assume that labor income is taxed at rate $\tau_{t}$ per period, and the tax revenues are rebated in a lump-sum fashion to the household. Assume that output is produced according to a Cobb-Douglas production function,

$$
\begin{equation*}
Y_{t}=K_{t}^{\alpha}\left[A_{t} L_{t}\right]^{(1-\alpha)}, \tag{9}
\end{equation*}
$$

where the technology term follows:

$$
\begin{equation*}
\ln A_{t}=\bar{A}+g t+\tilde{A}_{t} . \tag{10}
\end{equation*}
$$

The stochastic component of technology $\tilde{A}_{t}$ is assumed to follow an autoregressive process of order one. Markets are competitive. The household owns the capital of the firm, and decides how much to invest each period, $I_{t}$. This is equivalent to deciding how much capital, $K_{t+1}$, to save for next period. The household earns capital income: $R_{t} K_{t}=\left(r_{t}+\delta\right) K_{t}$
(a) (10 Points) Set up the representative firms problem, find the first-order conditions, and provide an economic interpretation.
(b) (10 Points) Write down the household's problem and derive its first order necessary conditions. Hint: We know the variables today with certainty, i.e. $E\left[x_{t}\right]=x_{t}$ but future variables are uncertain.
(c) (10 Points) Derive three relationships: (i) between consumption today and consumption tomorrow, (ii) between leisure today and leisure tomorrow, (iii) between consumption today and leisure today.
(d) (10 Points) Find the equations that describe labor supply and demand.
(e) (10 Points) How is the current level of consumption affected if the covariance between $1 / c_{t+1}$ and $r_{t+1}$ increases. Explain.
(f) (10 Points) Consider the deterministic version of the model (no uncertainty). How does the relative choice of labor supply between the two periods depend on the relative taxes between periods? Provide intuition for your answer. Do we have Richardian Equivalence.
